

Practice Quiz: Body Science — Module 03:

Perception

Name: ____ Date: ____

Part A: Multiple Choice

1. Your eyes send raw light signals to your brain. Your brain then:

A) Records them perfectly like a camera B) Combines those signals with predictions to build its best guess of what you're seeing C) Ignores most signals D) Only uses signals from one eye at a time

1. You have a blind spot in each eye where the optic nerve connects, but you never notice it. Why?

A) The blind spot is too small to matter B) Your brain fills in the missing information with predictions based on the surrounding scene C) You don't actually have a blind spot D) Your other senses compensate completely

1. Pain perception is an example of your body:

A) Recording damage like a sensor with no interpretation B) Interpreting signals — your brain uses context and predictions to decide how much something should hurt C) Always feeling the same amount of pain from the same injury D) Something that has no connection to the brain

1. A soldier in battle gets injured but doesn't feel pain until after the fight is over. This shows that:

A) Pain is fake B) The brain can adjust pain perception based on predictions about what matters most right now — survival first, pain later C) Soldiers can't feel pain D) Injuries don't actually hurt

1. Your sense of balance (vestibular system) combines signals from your inner ear, your eyes, and your muscles. This is called:

A) Having too many senses B) Multisensory integration — your brain combines multiple sources of information to build a more accurate prediction C) A glitch in the system D) Something only gymnasts need

1. When you spin around and then stop, you feel dizzy because:

A) Your brain is broken B) Your inner ear signals say you're still moving, but your eyes say you've stopped — your brain gets conflicting predictions C) Dizziness has no explanation D) Your eyes aren't working

1. Your body has sensors called proprioceptors in your muscles and joints that tell your brain where your body parts are. Without looking, you can touch your nose because:

A) Your nose is easy to find B) Your brain builds a body map from proprioceptive predictions, so it knows where your hand and nose are in space C) You memorized where your nose is D) This only works if you can see

Part B: Short Answer

1. Explain how **pain** is not just a simple signal but an act of **perception**. Give an example where the same injury might feel more or less painful depending on the situation. What role do your brain's predictions play?
2. When you get motion sickness (like in a car), your eyes say you're sitting still but your inner ear says you're moving. Explain this as a **conflict between predictions** from different senses. Why does this conflict make you feel sick?

3. Describe how your body uses **multiple senses together** (like sight, touch, and balance) to perceive something as simple as walking across a room. What would happen if one of those senses suddenly gave wrong information?
